Depth-First Search (DFS) Properties

What nodes DFS expand?

- Some left prefix of the tree.
- Could process the whole tree!
- If m is finite, takes time O(b^m)
- How much space does the fringe take?
 - Only has siblings on path to root, so O(bm)
- Is it complete?
 - m could be infinite, so only if we prevent cycles (more later)
- Is it optimal?
 - No, it finds the "leftmost" solution, regardless of depth or cost

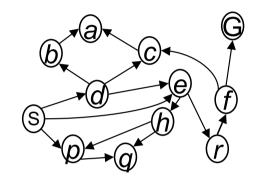

Breadth-First Search

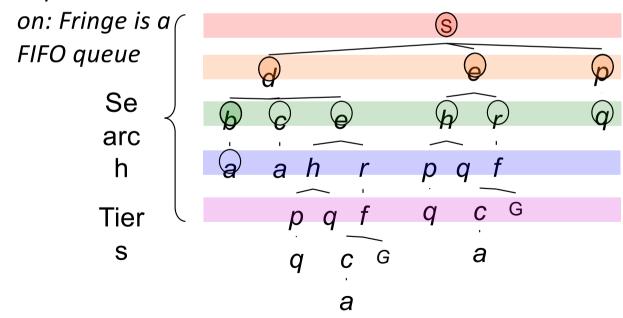

Breadth-First Search

Strategy: expand a shallowest node first

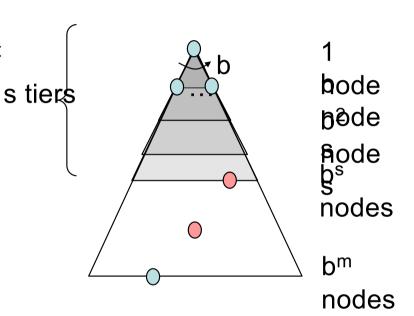

<u>Implementati</u>

Breadth-First Search (BFS) Properties

- What nodes does BFS expand?
 - Processes all nodes above shallowest solution
 - Let depth of shallowest solution be s
 - Search takes time O(b^s)
- How much space does the fringe take?
 - Has roughly the last tier, so O(b^s)
- Is it complete?
 - s must be finite if a solution exists, so yes!
- Is it optimal?
 - Only if costs are all 1 (more on costs later)

Quiz: DFS vs BFS

Quiz: DFS vs BFS

When will BFS outperform DFS?

When will DFS outperform BFS?

Iterative Deepening

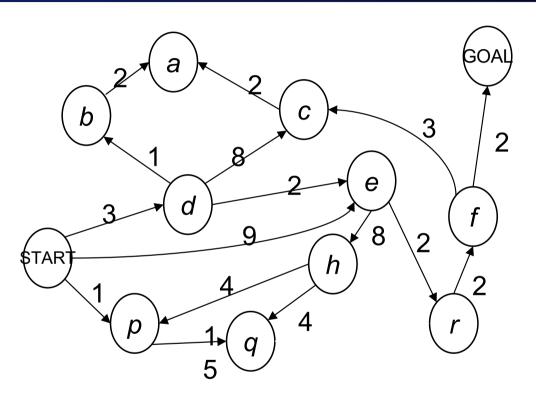

- Idea: get DFS's space advantage with BFS's time / shallow-solution advantages
 - Run a DFS with depth limit 1. If no solution...
 - Run a DFS with depth limit 2. If no solution...
 - Run a DFS with depth limit 3.

Generally most work happens in the lowest level searched, so not so bad!

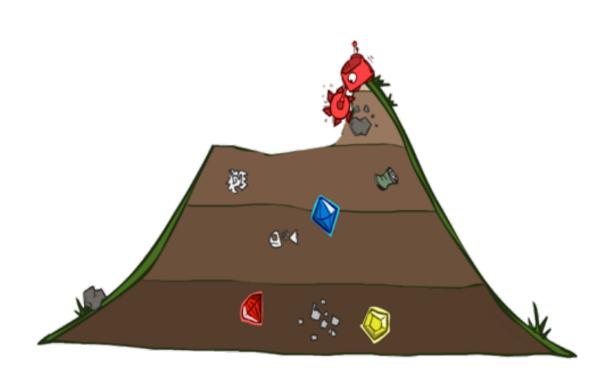

Cost-Sensitive Search

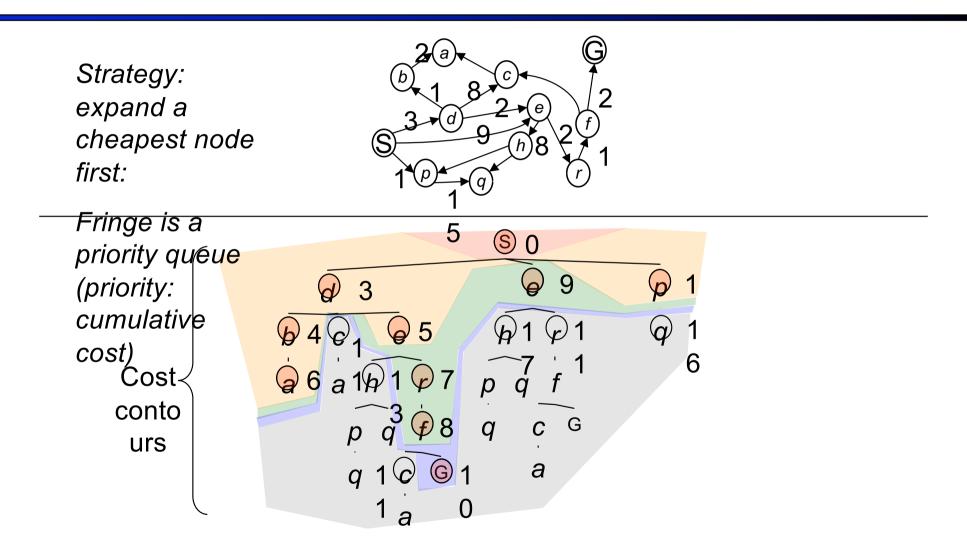

BFS finds the shortest path in terms of number of actions. It does not find the least-cost path. We will now cover a similar algorithm which does find the least-cost path.

Uniform Cost Search

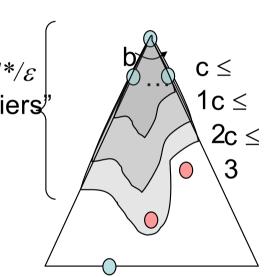

Uniform Cost Search

Uniform Cost Search (UCS) Properties

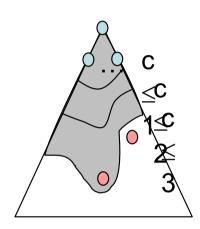

- What nodes does UCS expand?
 - Processes all nodes with cost less than cheapest solution!
 - If that solution costs C^* and arcs cost at least ε , then the "effective depth" is roughly C^*/ε
 - Takes time $O(b^{C*/\varepsilon})$ (exponential in effective depth)
- How much space does the fringe take?
 - Has roughly the last tier, so $O(b^{C^*/\varepsilon})$
- Is it complete?
 - Assuming best solution has a finite cost and minimum arc cost is positive, yes!
- Is it optimal?
 - Yes! (Proof via A*)

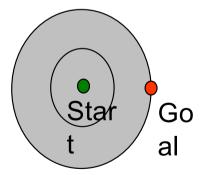

Uniform Cost Issues

Remember: UCS explores increasing cost contours

The good: UCS is complete and optimal!

- The bad:
 - Explores options in every "direction"
 - No information about goal location
- We'll fix that soon!

The One Queue

- All these search algorithms at the same except for fringe strategies
 - Conceptually, all fringes are priority queues (i.e. collections nodes with attached priorities)
 - Practically, for DFS and BFS, yo can avoid the log(n) overhead from an actual priority queue, using stacks and queues
 - Can even code one implementation that takes a variable queuing object

Search and Models

- Search operates over models of the world
 - The agent doesn't actually try all the plans out in the real world!
 - Planning is all "in simulation"
 - Your search is only as good as your models...
