Geometric (Hyper)Graphs

1-D "Estimation of Location"

$$x_5 \qquad x_1 \qquad\qquad x_6 \quad x_2 \quad x_3 \qquad x_7 \qquad x_4$$
x

Measurements x_i with some "tolerance" (maximum error")

1-D "Estimation of Location"

Measurements x_i with some "tolerance" (maximum error")

1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

X

Hypothesis – this is the location – how
many measurements support this?
Measurements x_i with some "tolerance" (maximum error")

1-D "Estimation of Location"

Hypothesis – this is the location – how
many measurements support this?
Measurements x_i with some "tolerance" (maximum error")

1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

x

Hypothesis – this is the location – how

Measurements x_i with some "tolerance" (maximum error")

1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

X

Hypothesis – this is the location – how
many measurements support this?

Measurements x_i with some "tolerance" (maximum error")

# 1-D "Estimation of Location"

Hypothesis – this is the location – how many measurements support this?
Measurements x_i with some "tolerance" (maximum error")
1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

x

Hypothesis – this is the location – how many measurements support this?

Measurements x_i with some "tolerance" (maximum error")

1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

X

Hypothesis – this is the location – how many measurements support this?

Measurements x_i with some "tolerance" (maximum error")
1-D "Estimation of Location"

MaxCon solutions (infinitely many of them – supported by 3 measurements)

Measurements x_i with some "tolerance" (maximum error")

Maximum Consensus solution – pick a solution with maximum agreement/consensus. In this example there are a range of solutions with support of 3 data points. All other hypotheses have 2 or less supporting data points.
1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

x

MaxCon solutions (infinitely many of them – supported by 3 measurements)

Measurements x_i with some "tolerance" (maximum error")

This is an example of "interval stabbing" – think of the hypotheses as vertical stabbing "pins" and how many tolerance intervals stabbed as a given position is the measure of how good the solution is.

1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

X

MaxCon solutions (infinitely many of them – supported by 3 measurements)

Measurements x_i with some "tolerance" (maximum error")

Interval stabbing is a useful way of thinking of many problems – particularly problems that come from computational geometry.
1-D "Estimation of Location"

x_5 x_1 x_6 x_2 x_3 x_7 x_4

X

MaxCon solutions (infinitely many of them – supported by 3 measurements)

Measurements x_i with some "tolerance" (maximum error")

But what has this to do with (hyper)graphs??

1-D "Estimation of Location"

MaxCon solutions (infinitely many of them – supported by 3 measurements)

Measurements x_i with some "tolerance" (maximum error")

Well multiple intervals can be stabbed iff they all overlap.
So...the space of possible solutions (with their scores) is described by the intersection pattern of the intervals.

Moreover *in this situation* three intervals overlap iff they *pairwise overlap* (this might seem like it is always a true statement but NOT for the intersection patterns of other object – in general – see later...)

1-D "Estimation of Location"

MaxCon solutions (infinitely many of them – supported by 3 measurements)

Measurements x_i with some "tolerance" (maximum error")

Well multiple intervals can be stabbed iff they all overlap.
So...the space of possible solutions (with their scores) is described by the intersection pattern of the intervals.

Moreover *in this situation* three intervals overlap iff they *pairwise overlap*

So.....the *pairwise* intersections tell the whole story. I can "smell" a graph!
The graph of pairwise intersections....

1-D "Estimation of Location"

MaxCon solutions (infinitely many of
them – supported by 3 measurements)
Measurements x_i with some "tolerance" (maximum error")

So.....the *pairwise* intersections tell the whole story. I can "smell" a graph!
The graph of pairwise intersections....

Assign a vertex to each interval/data point. Join the vertices of the intervals
pairwise intersect...

The MaxCon solutions are where the maximum number of vertices in the
graph all pairwise are joined by edges (the intervals pairwise intersect).
Maximum Clique problem!!!

1-D "Estimation of Location"

MaxCon solutions (infinitely many of them – supported by 3 measurements)

Measurements x_i with some "tolerance" (maximum error")

So.....the *pairwise* intersections tell the whole story. I can "smell" a graph!
The graph of pairwise intersections....

Now that we have decided that a 1-D estimation of location problem
(MaxCon) – can be described by a graph – a natural question is –
What type of graph can arise this way? Any graph? Only some graphs? If so
*which* graphs and what are their properties?

1-D "Estimation of Location"

MaxCon solutions (infinitely many of them – supported by 3 measurements)
Measurements x_i with some "tolerance" (maximum error")

So.....the *pairwise* intersections tell the whole story. I can "smell" a graph!
The graph of pairwise intersections....

What type of graph can arise this way? Any graph? Only some graphs? If so *which* graphs and what are their properties?

It turns out that this type of graph arose from other considerations – e.g., timetabling – where one might want to *minimize* overlap. Or scheduling where one might want to ensure some overlaps (train arriving and another leaving so passengers can transfer...

So…..the *pairwise* intersections tell the whole story. I can "smell" a graph!
The graph of pairwise intersections….

What type of graph can arise this way? Any graph? Only some graphs? If so *which* graphs and what are their properties?

The calls is called Interval class of graphs. Well, actually, since our intervals are equal sized, our examples are a subclass – "unit interval graphs". Look them up!
